ABSTRACT: The adhesion receptor P-selectin has long been known to support leukocyte rolling and emigration at sites of inflammation. Recently, P-selectin was also revealed to be a key molecule in hemostasis and thrombosis, mediating platelet rolling, generating procoagulant microparticles containing active tissue factor and enhancing fibrin deposition. Elevated levels of plasma \*\*\*p\*\*\* - selectin are indicative of thrombotic disorders and predictive of future cardiovascular events. Because the interaction between \*\*\*p\*\*\* - selectin and its receptor P-selectin glycoprotein ligand-1 (PSGL-1) represents an important mechanism by which P-selectin induces the formation of procoagulant microparticles and recruits the microparticles to thrombi, anti-thrombotic strategies are currently aimed at inhibiting this interaction. Recent developments also suggest that the procoagulant potential of P-selectin could be used to \*\*\*treat\*\*\* coagulation disorders such as \*\*\*hemophilia\*\*\* A.

ABSTRACT: High plasma levels of soluble P-selectin are associated with thrombotic disorders and may predict future cardiovascular events. Mice with high levels of soluble \*\*\*p\*\*\* - selectin have more microparticles in their plasma than do normal mice. Here we show that chimeras of \*\*\*p\*\*\* - \*\*\*selectin\*\*\* and immunoglobulin (P-sel-Ig) induced formation of procoagulant microparticles in human blood through P-selectin glycoprotein ligand-1 (PSGL-1; encoded by the Psgl1 gene, officially known as Selpl). In addition, Psgl1-/- mice produced fewer microparticles after P-sel-Ig infusion and did not spontaneously increase their microparticle count in old age as do wild-type mice. Injected microparticles specifically bound to thrombi and thus could be involved in thrombin generation at sites of injury. Infusion of P-sel-Ig into \*\*\*hemophilia\*\*\* A mice produced a 20-fold increase over control immunoglobulin in microparticles containing tissue factor. This significantly improved the kinetics of fibrin formation in the hemophilia A mice and normalized their tail-bleeding time. P-sel-Ig \*\*\*treatment\*\*\* could become a new approach to sustained control of bleeding in \*\*\*hemophilia\*\*\* .

ABSTRACT: Activation of platelets and coagulation in vivo was studied in  
nine patients with hemophilia A and inhibitors to human Factor  
VIII, prior to and following treatment with porcine Factor VIII  
(PFVIII; HYATE:C). In addition, six hemophiliac patients were similarly  
studied after \*\*\*treatment\*\*\* with recombinant Factor VIII (rFVIII).  
Platelet activation was also examined in vitro using porcine von  
Willebrand factor (PvWF)-enriched and PvWF-depleted fractions  
obtained by fractionation of PFVIII. Coagulation was assessed by  
measuring the concentrations of plasma prothrombin fragment 1+2  
concentrations (prothrombinase generation) and Factor Xa-ATIII. Patients  
treated with PFVIII had significantly increased numbers of  
circulating platelets expressing CD62 and CD63 (markers of platelet  
activation) and annexin V (marker of platelet procoagulant activity)  
compared to patients treated with rFVIII; the former patients also  
demonstrated an increase in plasma coagulability after \*\*\*therapy\*\*\*. In  
in vitro experiments it was observed that the platelet-activating and  
procoagulant capacity of PFVIII resided in the PvWF-enriched fraction,  
and the same was true for the plasma hypercoagulability following  
exposure of platelets to PFVIII. These results support the hypothesis  
that PFVIII-induced platelet activation provides a mechanism for  
enhancing hemostasis, separate from, and additional to, that due to  
increased circulating Factor VIII, and it is due to residual PvWF in the  
PFVIII preparation.

ABSTRACT: Previously we reported that soluble P-selectin (sP-sel) is a direct inducer of pro-coagulant activity, as it promotes the formation of pro-coagulant microparticles in blood (Andre, P., Hartwell, D., Hrachovinova, I., Saffaripour, S., and Wagner, D.D. PNAS, 2000, 97:13835-13840). Since some of these microparticles express tissue factor (TF), we decided to investigate the possible therapeutic potential of sP-sel in treatment of hemostatic defects present in factor FVIII-/- mice ( \*\*\*hemophilia\*\*\* A mice). In hemophilia A, thrombin generation depends on the factor VII/TF pathway, since factor VIII is deficient. \*\*\*Hemophilia\*\*\* A mice (Bi, L., Lawler, A.M., Antonarakis, S.E., High, K.A., Gearhart, J.D., Kazazian, H. H. Nature Genetics, 1995, 10:119-121) were injected in tail vein with soluble murine P-selectin-Ig (P-sel-Ig) chimera or IgG1 control (1.2 mug/g body weight) and we measured tail bleeding time six hours later. All P-sel-Ig \*\*\*treated\*\*\* mice (n=8) stopped bleeding within three minutes (1.5+-0.25 min), while five out of eight IgG1-treated mice did not stop bleeding by 15 minutes when their tails were cauterized. Thus bleeding time was significantly ( $p<0.005$ ) shorter in P-sel-Ig injected mice than in IgG1 controls. In another experiment eleven hemophilia A mice infused with P-sel-Ig and seven mice infused with IgG1 were bled into ACD six hours after \*\*\*treatment\*\*\*. Activated partial thromboplastin time (APTT) and recalcified clotting time were determined in platelet poor plasma. Both APTT and clotting time were significantly shorter ( $p<0.006$ ) in P-sel-Ig \*\*\*treated\*\*\* mice. Shorter APTT in P-sel-Ig \*\*\*treated\*\*\* mice (31.7+-0.7 vs. 37.9+-1.6 seconds) indicates a higher level of TF-bearing microparticles in plasma. To verify this, microparticles were isolated from the plasma, stained for TF and flow cytometry analysis was performed. 10,000 events were counted to determine the population of TF-positive microparticles. We found that hemophilia A mice treated with P-sel-Ig had, on average, seven times more TF-positive microparticles (14.2+-1.65%) than mice \*\*\*treated\*\*\* with IgG1 (1.9+-0.3%). The difference was statistically significant ( $p<0.001$ ). We conclude that sP-sel can improve bleeding and coagulation parameters in hemophilia A mice and thus could be considered as an adjunctive treatment for patients with a congenital bleeding disorder such as \*\*\*hemophilia\*\*\*.

PSGL-1 is a major counterreceptor of all three types of selectins that is expressed in several leukocyte subsets. Data presented, here prove that this mucin may be implied in haematological disorders. We established on normal peripheral blood and in samples derived from 20 AML patients that PSGL-1 is differently expressed in various leukocyte subsets. Myeloblasts appearing in acute myeloid leukaemia patients express significantly less PSGL-1 (12 000 +/- 5300) than mature neutrophils ( $p < 0.001$ ). In monocytic

leukaemias, however, the amount of PSGL-1 on monocytic precursors is displayed in a fairly broad range which was not significantly different from that of mature monocytes ( $p=0.084$ ). Monoblasts/promonocytes possess more PSGL-1 than myeloblasts and the expression pattern is completely non-overlapping. This would imply a differential expression of PSGL-1 during myeloid haemopoietic development and suggests, that the quantitation of surface PSGL-1 may help in differentiating myeloblasts from monoblasts by immunophenotyping in different AML subsets. PSGL-1 has also a certain role in the generation of procoagulant microparticles (MP) as in the PSGL-1 knockout mouse the MP number failed to increase with age and the MP contained significantly less tissue factor than wild type mice. Since PSGL-1 P-selectin interaction is crucial in generating a procoagulant effect we tested the hypothesis that the administration of a P-selectin IgG chimera (Psel-Ig) corrects bleeding tendency in a murine haemophilia model and in human haemophilic blood. The addition of Psel-Ig resulted in significant improvement of the bleeding tendency in mice and in the generation of MP in human hemophilic blood. Thus, the Psel-Ig can become an alternative route to control bleeding tendency in coagulopathies.

Haemostasis and inflammation are tightly linked reactions primarily designated as post-traumatic protection mechanisms. Both reactions require the recruitment of specialized cells with specific functions. Recruitment of cells from circulating blood is a precisely regulated, receptor-mediated process that prevents inadvertent (e.g. thrombosis) and insufficient (e.g. bleeding) effects. \*\*\*p\*\*\* - \*\*\*selectin\*\*\* is a leukocyte-adhesion receptor but is also expressed on platelet and endothelial cell surfaces. It promotes interactions of leukocytes with platelets and endothelial cells, enabling leukocyte and platelet rolling on activated endothelial surfaces. Endothelial rolling of circulating cells represents an intermediate step before firm adhesion that still enables detachment.

Hemophilia B was recognized as a good candidate for gene  
\*\*\*therapy\*\*\*. Several strategies have been attempted and gave promising results in hemophilic animals but failed to achieve corrective levels in humans. To overcome this inconvenience we aimed to generate intracellular pools of factor (F)IX in cells that are implicated in the hemostatic response, e.g. endothelial cells and platelets. Upon stimulation, these cells release their granule content, which in this case would result in an increase in local FIX concentration, and could locally produce an effective  
\*\*\*hemostasis\*\*\*. In an attempt to produce an intracellular pool of releasable coagulation FIX, the cytoplasmic domain of the P-selectin (pselCT) molecule was fused to the carboxy-terminal extremity of the human FIX protein. The properties of this chimeric molecule (FIX-pselCT) were studied in AtT20, a cell line which possesses storage granules. As previously shown for transmembrane molecules but not for a soluble protein such as FIX, the pselCT fragment induces the storage of FIX-pselCT. The coagulant activity of FIX-pselCT was not affected by the addition of the pselCT tail. The \*\*\*treatment\*\*\* of AtT20 cells with different inhibitors revealed that FIX-pselCT was not submitted to intracellular degradation and that the half-life of the chimeric molecule was at least two times longer than that of FIX-WT. An immunoelectron microscopic analysis demonstrated a specific localization of FIX-pselCT within the ACTH-containing granules. Cell stimulation using Phorbol Myristate Acetate (PMA), ionophore A-23187 or 8-Br-cAMP induced efficient release of an active FIX-pselCT. These data demonstrate that the addition of the cytoplasmic domain of P-selectin to FIX modifies the cellular fate of the FIX molecule by directing the recombinant protein toward regulated-secretory granules without altering its coagulant activity.
